40 **Abstract**

41 Sprinting and speed is a fundamental skill and physical attribute crucial in seam bowlers and batters
42 within cricket. The aim of this study was to assess differences in mechanical properties during sprinting
43 between youth and senior international cricketers and between seam bowlers and batters.
44 Retrospective 40m sprint times and anthropometric measures of 56 international cricketers (19 senior
45 seam bowlers, 7 under-19 seam bowlers, 16 senior batters, 14 under-19 batters) were used to
46 calculate the theoretical maximal force (F_0), theoretical maximal velocity ($V_{(0)}$), theoretical maximal
47 power (P_{max}), slope of the force-velocity relationship (F-V slope), maximal ratio of horizontal-to-
48 resultant force (RF_{max}), decrease in the ratio of horizontal-to-resultant force (DRF) and optimum
49 velocity (V_{opt}). There were no significant ($P > 0.05$) differences in sprint times nor sprint mechanical
50 profile variables between position or age. However, there was a *moderately* greater F_0 (N/Kg) (ES =
51 0.78; 90% CI 0.19 - 1.34) and RF_{max} (ES = 0.75; 90% CI 0.11 - 1.35) in senior seam bowlers when
52 compared to batters. Furthermore, FV Slope (ES = 0.79; 90% CI 0.15 - 1.40) and DRF (ES = 0.75; 90% CI
53 0.11 - 1.35) were *moderately* greater in senior compared to under-19 batters. When expressed relative
54 to body mass, it appears that senior international seam bowlers show trends towards a more force
55 biased profile during sprinting when compared to batters. These findings will help coaches to optimise
56 physical preparation strategies in youth and senior international cricketers.

73

74 Introduction

75 Cricket is a team sport that has three competitive formats (multi-day, one-day and Twenty20) with
76 competition lasting between 3 h (Twenty20) and 5 days (multiday)¹. The demands of cricket vary
77 between match format and position (batters, seam bowlers and wicketkeepers)², as noted by the
78 greater number of high intensity efforts during Twenty20 when compared to other formats².
79 Furthermore, seam bowlers cover between 20-80% more distance and perform high intensity
80 locomotive activities up to 8 times more often compared to other positions (batters, spinners and
81 wicketkeepers) across cricket game formats². However, all positions and game formats require
82 noteworthy volumes of maximal accelerations and high intensity running²⁻⁴. Consequently,
83 understanding and optimising the mechanical properties of sprint acceleration profiles is vital in
84 improving the efficiency of sprinting and performance in cricket.

85

86 Over recent years, sprint acceleration profiles (up to 40m) have been recorded using timing gates or
87 a radar gun and modelled to evaluate the mechanical properties of force application during sprinting
88^{5, 6}. Employing the aforementioned methods enables determination of the force-velocity-power
89 profile to be derived from the acceleration-time curve. This assessment allows coaches and sport
90 scientists to assess biomechanical limitations of over ground sprint acceleration in the field. The
91 biomechanical model is an analysis of the sprinters' kinematics and kinetics during the acceleration
92 phase of sprinting. The model is practically convenient, only requiring anthropometric and
93 spatiotemporal data to be collected by the practitioner. An inverse dynamic approach is then applied
94 to the centre of mass, to allow for the analysis of sprinting⁵. Theoretical maximal force (F_0), theoretical
95 maximal velocity (V_0), theoretical maximal power (P_{max}), slope of the force-velocity relationship (F-V
96 Slope), maximal ratio of horizontal-to-resultant force (RF_{max}), decrease in the ratio of horizontal-to-
97 resultant force (DRF) and optimum velocity (V_{opt}) are all derived from the acceleration-time curve.
98 Until recently^{7, 8}, the mechanical properties of sprinting have only been assessed in a limited variety
99 of sport such as soccer⁹⁻¹¹, rugby¹², American football¹³ and in world class sprinters¹⁴. Sprint
100 mechanical reference values now exist across a multitude of different sports, playing level and gender
101^{7, 8}, with notable differences observed. However, none have been documented within cricket.

102

103 Given the large difference in physiological demands of positional roles within an American football
104 team¹⁵, it is unsurprising that differences in mechanics were reported within a sample of 1254 athletes
105¹³. However, differences in sprint mechanics were only found between positions that were either
106 heavily dependent or not dependent on running. This study in American football appears to be the
107 only analysis of mechanical profiling across different positions within a specific sport. Understanding

108 the optimal mechanical profile for specific positions will assist coaches in developing individual and
109 position specific training programmes.

110

111 The demands of seam bowling and batting (as assessed via time motion analysis) vary substantially ^{2,}
112 ³. Batting consists of sprinting 20.2m with 180° turns ¹⁶. During an innings, batters can perform in
113 excess of 40 turns ¹⁶ and in Twenty20 cricket perform a mean sprint distance of 14m with a mean rest
114 period of 53s between sprints ¹⁷. Seam bowlers are exposed to greater volumes of high intensity linear
115 running compared to all other positions ^{2,3}, partly due to run up speeds being as high as 6.8 m·s⁻¹ ¹⁸.
116 These differences between positions may influence the mechanical sprint profiles of seam bowlers
117 and batters. Research has demonstrated that it is advantageous for seam bowlers to be taller than
118 other positions in international cricket, as greater stature can increase factors such as the bounce of
119 the ball from the pitch ¹⁹. With this increase in stature, body mass is expected to be greater, thus
120 requiring a greater application of force during sprinting compared to batters (who are likely lighter)
121 to produce the same sprint speeds. Therefore, the aim of this study is to investigate differences in the
122 acceleration sprint mechanical profiles of international seam bowlers and batters. A secondary aim of
123 the study was to assess differences between age group and senior international cricketers, as
124 differences between the anthropometric characteristics of batters and seam bowlers may influence
125 the mechanical properties of sprinting. A final aim of the study was to explore differences in stature
126 and body mass between batters and seam bowlers across age groups.

127

128

129 **Methods**

130 **Participants**

131 Fifty-six (mean ± SD age; 22 ± 4 years, stature; 1.84 ± 0.07m, body mass; 81.2 ± 9.3 kg) senior and
132 under-19 international cricketers took part in the study. Players were separated into four groups
133 based on their position and competition level (senior batters, n = 16; senior seam bowlers, n = 19;
134 under-19 batters, n= 14; under-19 seam bowlers n = 7). Figure 1 shows the mean ± SD and individual
135 characteristics across each group. Senior international cricketers were defined as being involved in
136 the Senior International Pathway Programme (either Lions or Senior Men), whereas under-19
137 cricketers were only involved in the under-19 programme.

138

139 All athletes avoided strenuous exercise in the 24 hours before performance testing and were free from
140 musculoskeletal injury for three months prior to data collection. The study was based on pre-existing
141 data sets from physical performance testing days between 01/10/2018 – 01/07/2019. Data were

142 collected as a part of routine physical athlete profiling with athletes and parents of under-18
143 cricketers' consenting to its use for research purposes. Retrospective ethics was granted through the
144 local ethics committee, in agreement with the Declaration of Helsinki.

145

146 Procedures

147 The study was a cross-sectional analysis comparing the mechanical sprint profiles between position
148 (seam bowlers Vs batters) and playing level (age group international Vs senior international). Sprint
149 performance was assessed over 10, 20, 30 and 40m and all tests were performed on the same 60m
150 indoor cricket training surface. As 30m split times were not collected from 5 players, only 10, 20 and
151 40m raw sprint times have been reported in this manuscript, however all available sprint times were
152 used in the F-V acceleration profile analysis. Participants wore suitable running trainers which had
153 been used previously by the athletes in maximal sprinting training sessions. Prior to testing,
154 participants performed a group warm-up delivered by the Strength and Conditioning Coach. All warm-
155 ups consisted of 4-5 progressive sprints, building from 60 to 100% maximal effort. Following the warm-
156 up and 3-5 min rest, three maximal 40m sprints were performed with 4 min rest between each sprint.
157 Participants started in a split stance position 50 cm behind the start line with the head and chest within
158 10 cm of the first beam.

159

160 The fastest 40m sprint time and participants body mass was used for analysis. F_0 , V_0 , P_{max} , F-V slope,
161 RF_{max} , DRF and V_{opt} were calculated using a published and custom built spreadsheet²⁰. The
162 aforementioned variables are calculated from the mono-exponential function of the velocity time
163 curve generated from the sprint split times entered on the custom-built spreadsheet²⁰. This is derived
164 from the least-squared regression fitting procedure. Force velocity linear relationships were
165 calculated using horizontal acceleration of the participants' centre of mass (from running velocity
166 change over time) and ground reaction forces from body mass and aerodynamic friction.
167 Consequently, F_0 and V_0 are calculated as the x and y intercepts from the force velocity regression,
168 where the F-V slope is calculated. P_{max} was calculated as $(F_0 \cdot V_0 / 4)$ and RF_{max} as the maximal horizontal-
169 to-resultant force after 0.3s (beginning phase of the sprint). DRF was calculated as the linear decrease
170 in RF (or ability to maintain a high RF during the acceleration^{22,23}). For specific calculations details see
171 Morin and Samozino²¹ and Samozino et al.⁵.

172

173 Dual beam timing lights (Brower TC, Brower Timing System, Utah, USA) were placed at 0, 10, 20, 30
174 and 40m. The first timing gate was placed at the start line, mounted on tripods 1.0m above ground

175 level, while the remaining timing gates (10 – 40m) were mounted 1.3m above ground level. Prior to
176 sprinting body mass was recorded using SECA 862 Scales (Birmingham, UK).

177

178 Statistical Analyses

179 Data were analysed using SPSS (version 24.0, Chicago, Illinois, USA) and presented as mean \pm standard
180 deviation (SD). Visual inspection of the Q-Q plots and boxplots were used to assess the assumptions
181 of normality. Levene's test was used to check for homogeneity of variance before analyses. To detect
182 differences between age (youth, senior) and positions (seam bowlers, batters) a 2 x 2 ANOVA was
183 conducted. Alpha level was set at 0.05. If significant interactions were detected, *pairwise* comparisons
184 using a Bonferroni *post hoc* were performed with 90% confidence intervals (CI). The standardised
185 magnitude of effect (ES)²⁴ difference was examined between groups (senior seam bowlers, under-19
186 seam bowlers, senior batters, under-19 batters). Based on data collected from elite experienced
187 athletes²⁵ ES were set as trivial (<0.25), small (0.25-0.50), moderate (0.50-1.00), or large (>1.00).

188

189 Results

190 There was no significant ($P > 0.05$) difference in sprint times (10, 20 and 40m) between positions and
191 age (Table 1). However, there was a trend towards a *moderately* quicker ($ES > 0.50$) sprint time across
192 all distances for senior seam bowlers when compared to under-19 seam bowlers. Senior seam bowlers
193 also exhibited a *moderately* quicker time compared to senior batters across 10m ($ES\ 0.53$; $CI\ -0.05 -$
194 1.09) and 20m ($ES\ 0.54$; $CI\ -0.04 - 1.09$).

195

196 There was a significant difference in body mass between positions ($F_{(1,52)} = 8.6$; $P < 0.01$; $\eta_p^2 = 0.14$)
197 and age ($F_{(1,52)} = 12.5$; $P < 0.001$; $\eta_p^2 = 0.19$). Figure 1 shows a significantly higher body mass in seam
198 bowlers compared to batters ($P < 0.01$; $CI\ 2.7 - 9.9\ kg$) and senior compared to youth cricketers ($P <$
199 0.01 ; $CI\ 3.9 - 11.2\ kg$). Stature was also significantly ($F_{(1,52)} = 15.8$; $P < 0.001$; $\eta_p^2 = 0.23$) different
200 between positions (Figure 1) with seam bowlers being significantly taller compared to batters ($P <$
201 0.001 ; $CI\ 4.1 - 10.1\ cm$).

202

203 ****Insert Table 1 around here****

204

205 ****Insert Figure 1 around here****

206

207

208 There were no significant differences ($P > 0.05$) in any sprint mechanical variables. Individual and mean
209 responses are presented in Figure 2. The standardised effect size differences in sprint mechanical
210 force-velocity profile between position and age are presented in Tables 3 and 4.

217

218 Discussion

219 The aim of the study was to assess differences in the acceleration sprint mechanical profiles of seam
220 bowlers and batters across under-19 and senior international cricketers. The main findings of this
221 study were that despite the senior international bowlers exhibiting greater body mass and stature,
222 this was not detrimental to sprinting performance. Senior international seam bowlers even showed
223 trends towards a greater application of force, relative to body mass in sprinting compared to senior
224 batters. Furthermore, it was observed that senior batters have a trend towards a more velocity
225 dominant profile when compared to under-19 batters.

226

227 The results from this study showed no significant differences in the mechanical acceleration profiles
228 between positions and in under-19 compared to senior international cricketers. However, it should be
229 noted that there are a number of potential trends. Senior seam bowlers exhibited a *moderately* higher
230 F_0 (N/kg) (ES = 0.78; 90% CI 0.19 - 1.34) and RF_{max} (ES = 0.75; 90% CI 0.11 - 1.35) compared to senior
231 batters. As RF_{max} represents the ability to apply horizontal force during the early steps of acceleration
232 and F_0 (N/kg) represents the initial step during the start of the acceleration, it seems appropriate that
233 there are similar *moderately* greater values of F_0 (N/kg) and RF_{max} in senior seam bowlers compared
234 with senior batters. Higher F_0 (N/kg) and RF_{max} suggest that senior seam bowlers are able to generate
235 greater forces in the first few steps of sprinting. Senior seam bowlers have been shown to perform a
236 greater number of sprints across training, during Twenty20, one day and multiday cricket^{2, 3}. The
237 volume of sprinting the senior seam bowlers have been exposed to throughout their careers may
238 suggest why a *moderate* difference between positions at senior but not under-19 level was observed
239 here. Even though much of the high speed running performed by seam bowlers is submaximal and
240 could be considered lacking as an adaptation stimulus, previous research has shown improvements in
241 sprinting performance following submaximal high speed running²⁶. The greater F_0 (N/kg) and RF_{max} in

242 seam bowlers compared to senior batters cannot be solely explained by the longer and higher number
243 of high intensity accelerations actions during matches¹⁷ and training^{3,27} across a career. Seam bowlers
244 are exposed to up to 9 times body mass during the delivery phase of seam bowling²⁸. This exposure
245 can be over 300 times during a game, which over time is a considerable training stimulus, given
246 previous research has shown as little as 120 high load drop jumps per week for 10 weeks has enhanced
247 10m sprint times²⁹. As minimal sprinting kinematic differences have been demonstrated in fielding
248 positions³⁰, it is logical to suggest that the *moderate* differences in sprinting profiles are not fielding
249 related. It is hypothesised that consistent exposure to high forces contributes to the greater force
250 production capabilities observed here in senior seam bowlers compared to senior batters during the
251 acceleration of sprinting. However, this study was a cross-sectional analysis and reports no change in
252 F_0 and RF_{max} between under-19 and senior seam bowlers, further research examining the longitudinal
253 analysis of mechanical sprint profiles will assist in determining temporal changes between batters and
254 bowlers.

255

256 Previous work has reported differences in the mechanical sprinting profiles between numerous sports
257^{7, 8}. Acceleration and explosive sports such as bobsleigh, soccer and athletic jumping showed higher
258 RF_{max} and F_0 values⁷. Consequently, it is unsurprising that there are *moderately* greater RF_{max} and F_0
259 values in senior seam bowlers compared to senior batters. Whilst differences in sprint mechanical
260 profiles have been reasonably well established between sports, this study adds to the small body of
261 work assessing differences in positional sprint mechanical profiles¹³ and research in mechanically
262 similar sports such as rugby league compared to rugby union¹² and futsal compared to soccer¹¹. Based
263 on the findings from the current study and the aforementioned previous studies, it appears that force
264 velocity profiling may be appropriate to detect differences within and between mechanically similar
265 sports and positions.

266

267 There was a *moderate* increase in the F-V Slope (ES = 0.79; 90% CI 0.15 - 1.40) and DRF (ES = 0.75; 90%
268 CI 0.11 - 1.35) in the senior batters compared to the under-19 batters, despite no significant
269 differences. As DRF represents the maintenance of net horizontal force production with increasing
270 running speeds and has been shown to be almost perfectly correlated with differences in F-V slope⁷,
271 it is unsurprising both showed a *moderate* increase in the senior batters compared to the under-19
272 batters. It is unclear why senior batters have a more velocity dominant profile compared to under-19
273 batters. This trend was not seen in under-19 seam bowlers when compared to senior seam bowlers.
274 It may be there is a maximal force adaptive response to seam bowling from high forces exposed to
275 during each bowling delivery³¹ across playing years, that may explain less of a shift to a more dominate

276 velocity profile. The cross-sectional design of this study makes any conclusions around long term
277 adaptations from seam bowling or batting very speculative.

278

279 A *moderately* faster sprint time (10, 20 and 40m) in senior compared to under-19 seam bowlers and
280 in senior seam bowlers compared to senior batters was observed at 10m (ES = 0.53; 90% CI -0.05 -
281 1.09) and 20m (ES 0.54; CI -0.04 – 1.09). However, this was not significantly different. This is the first
282 study in cricket to identify that like other sports, sprint ability may be different between positions ³²⁻
283 ³⁴ and age³⁴. The uncorrected sprint times in this study are comparable to county cricket data ³⁵, but
284 are notably quicker than those previously reported in other senior ^{36,37} and academy county cricketers
285 ³⁸. Whilst cricket is highly skill dependant sport, it appears that there may be an enhancement in
286 physical capacities which are associated with international cricketers. Future research should look to
287 establish differences in demands and physical attributes of first class compared to international
288 cricket.

289

290 Unsurprisingly, seam bowlers were taller than batters. Specific studies have presented the stature of
291 first class ^{39,40} and international seam bowlers ⁴¹. This is the first study to present a comparison within
292 international under-19 and senior cricketers. Previous work has reported that anthropometric
293 characteristics correlate with ball release speed in seam bowlers ⁴⁰. Further highlighting the
294 importance of seam bowlers' stature, up to 80% of the wickets in international cricketers have been
295 from seam bowlers that are above 1.83m ¹⁹. Conversely, separate research has reported that
296 anthropometric characteristics have less of an influence on bowling performance in senior cricketers
297 ⁴². What is clear from our results is that the greater stature observed in seam bowlers does not reduce
298 sprint performance and may even contribute to enhancing sprint qualities. Other factors such as the
299 higher release angle of delivery are clearly advantageous characteristics associated with taller seam
300 bowlers ⁴³. It is difficult to determine the exact reason for the greater stature with seam bowlers, but
301 as athletes are subjectively selected for national teams, it is logical to suggest coaches' have a
302 preference towards taller bowlers. The taller seam bowlers observed in this study may also explain
303 the *moderately* quicker sprint times demonstrated in senior seam bowlers when compared to senior
304 batters. Elite sprinters have shown an historic increase in stature⁴⁴ with longer limbs suggested to be
305 an advantage in sprinting ⁴⁵. A subsequent increase in stride length would mean an increase in force
306 during the initial accelerations steps, which may explain the *moderately* greater in RF_{max} and F₀ values
307 in seam bowlers when compared to seam batters observed here. Further research investigating the
308 kinematic changes between positions in cricket would allow for more definite conclusions to be made.

309

310 There were differences in body mass between senior international and under-19 cricketers. The exact
311 composition of the greater body mass is open to speculation but the likely explanation is greater
312 muscle mass. Previous work has shown correlations between strength and bowling release speed ⁴²
313 and consequently large parts of the physical preparations strategy are targeted at increasing strength
314 ^{46, 47}. Other sports such as rugby have reported continued increases in body mass, and in some cases
315 stature until athletes reach their early 20's ⁴⁸. The lower body mass reported in the under-19 cricketers
316 may also be a result of the athletes continued growth. The greater body mass in the seam bowlers
317 compared to batters observed here is likely due to the seam bowlers being taller.

318
319 Although collection of the data was standardised between groups, there are some limitations in the
320 comparisons of the results presented here to other athletic populations. Within the current study,
321 sprint mechanical profiles were calculated retrospectively using timing gates. The use of timing gates
322 to assess sprinting profiles has been shown to be valid and reliable ⁴⁹. However, when using
323 retrospective sprint data from timing gates there are notable limitations ^{7,11}. For example, it is advised
324 participants are placed 5-10 cm directly behind the triggering beam so the initial horizontal movement
325 is captured. In previous work, 0.5s has been added to sprint times for all groups to compensate for
326 the first movement triggering ⁷. The same methodological approach was used in this study. However,
327 instructions were given to the participants to move their torso towards the beam. As a result, the 0.5s
328 may have over compensated for the forward momentum when the start beam was triggered and
329 comparing this data to other literature may not be appropriate. Previous literature that has not added
330 0.5s to the sprint times has reported an overestimation in F_0 data ¹³. Even though these data are
331 subjected to this limitation, the data offer a standardised position and age comparison in international
332 cricket within this population.

333
334 There a several notable practical applications for these data. The findings from this study will serve to
335 enhance the targeted prescription and planning of physical preparation strategies in cricket. Given
336 there are few differences in theoretical maximal force between under-19 senior bowlers and senior
337 batters, it is suggested that further targeted maximal force training may support the enhancement of
338 sprint acceleration. The data indicate a large variability in the sprint mechanical profiles within each
339 group (under-19 seam bowlers, under-19 batters, senior seam bowlers, senior batters), therefore
340 mechanical profile of individual athletes and individualised sprint programming of cricketers is advised
341 to maximise performance. Future research should focus on tracking longitudinal changes in the sprint
342 mechanics within the same individuals.

343

344 In summary, this study examined the differences in mechanical sprinting profiles between batters and
345 seam bowlers across senior and under-19 international cricketers. Whilst, there were no statistically
346 significant differences in the mechanical profiles of senior seam bowlers, *moderately* higher force
347 production when expressed relative to body mass was observed, despite a higher body mass in
348 international seam bowlers. This greater force is likely due to the regular exposure to high forces
349 experienced during seam bowling. Senior batters appear to demonstrate a more velocity bias
350 compared to under-19 batters. The precise reasons for these differences are currently unclear.
